Background

Banana streak virus (BSV) sequences are integrated into the nuclear genome of Musa balbisiana. There is strong experimental evidence that some of these BSV integrated sequences, called BSV endogenous pararetroviruses (BSV EPRVs), can give rise to infectious episomal BSV genomes upon stress conditions. Such stresses include interspecific genetic crosses, therefore this phenomenon represents a serious limitation to the creation of novel Musa hybrids between A (Musa acuminata) and B (Musa balbisiana) genomes and to the diffusion of such hybrids.

Methods

As part of an international effort within the Musa Genomics Consortium aimed at defining the integration patterns of BSV EPRV sequences into the nuclear genome of Musa species and the mechanisms leading to the activation of such BSV EPRVs, we have constructed and characterised three BAC libraries from M. acuminata Cavendish (AAA), M. acuminata Calcutta 4 (AA) and M. balbisiana PKW (BB) nuclear genomes, respectively.

Complete genomes of four different BSV strains (BSV-Ol “Obino L’Ewai”, BSV-Gf “Gold Finger”, BSV-Im “Imove”, BSV-Mys “Mysore”) were used as probes to screen the BAC libraries and FISH experiments were carried out to test for the presence of integrated viral sequences in Musa B chromosomes.

Results

Upon screening of the M. balbisiana PKW BAC library, 10 BAC clones positive for BSV-Ol, 9 for BSV-Gf, 26 for BSV-Mys and 24 for BSV-Im were identified. All positive BAC clones were distinct from each other. On the other hand, screening of either M. acuminata Calcutta 4 or M. acuminata Cavendish BAC libraries with the four complete viral sequences revealed that no BSV EPRVs related to the four analyzed strains were present in any of the two Musa A genomes analyzed.

BAC clones found positive upon screening were further characterized by BAC-end sequencing and RFLP-fingerprinting, and selected BACs containing BSV-Ol or BSV-Gf EPRV sequences were completely sequenced. Detailed analysis of the nucleotide sequences and chromosomal organization of BSV-Ol and BSV-Gf EPRV sequences within these BAC clones will be presented and discussed. This study represents the first step towards the characterization of the mechanisms leading to the activation of BSV EPRV sequences in Musa and the implementation of novel strategies to counteract this phenomenon.
