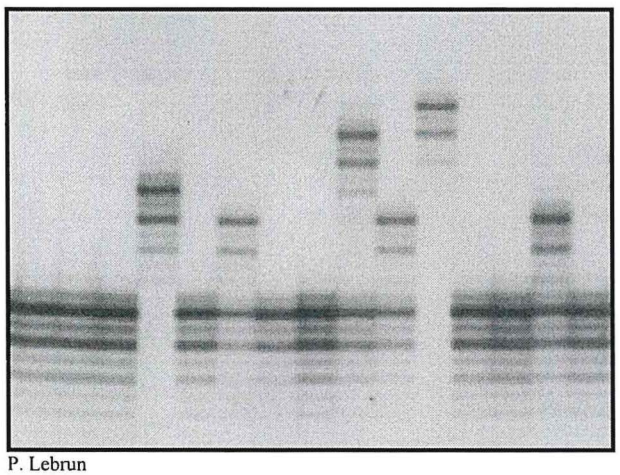
A Laboratory Manual



P. Lebrun

Ipri, Cogent, Burotrop, Cirad, CEE

I. Standardized techniques

1a: Collecting and storing plant material for molecular biology

1b: DNA extraction

1c: Quantification and dilution

1d: PCR Amplification

1e: Denaturing polyacrylamide gel electrophoresis

1f: Silver staining

1g: Reading and encoding the data

II. Microsatellite markers and standards

Allele size for the standard genotypes T1 et T2

I. Standardized techniques

1a: Collecting and storing plant material for molecular biology

COLLECTION OF PLANT MATERIAL

- If possible, collect the samples early in the morning, when the weather is not too warm.
- For each sample, collect several leaflets from the basis part of leaf 1,2 or 3 in order to obtain approximately 10-20 g fresh weight. Leaflets should be **green (not yellow)**, healthy, undamaged and without fungi or algae.
- Avoid crushing or damaging the leaflets whilst collecting.
- Label the samples correctly (: cultivar name, plantation date, tree identification and country of origin, collection date, name of the collector;) This is very important!
- Roll the leaflets in a bag plastic without crushing them.
- Leaves can be kept fresh in the refrigerator for a maximum of 4 weeks provided that they are not allowed to freeze or dry. For this reason, they must be placed into a sealed plastic bag.
- As soon as possible after collecting continue with the sections below.

TO DRY THE LEAFLETS

- Cut the leaflets into pieces, about 20cm long (6 pieces per sample are enough), do not remove the midrib or edge of leaflets.
- If you have an oven, put the leaflet pieces horizontally into the oven and leave to dry for 3 days at 33°C.
- If you do not have an oven, place the leaflet pieces horizontally on absorbent paper, in a cold or refrigerated room if possible, and leave to dry for at least one week.
- DO NOT PLACE THE LEAFLETS ON TOP OF EACH OTHER WHILST DRYING.
- After drying, put leaflets into paper bags, making sure that the samples are correctly labelled.
- Labels MUST include: cultivar name, plantation date, tree identification and country of origin., collection date, name of the collector;
- Before sending, keep dried leaflets in a dry place.

TO SEND THE LEAFLETS IMMEDIATELY WITHOUT DRYING

- Bend the entire leaflet so that it will fit into a plastic bag (cold storage bags are recommended). Put the leaflet into the plastic bag and close tightly, making sure that the bag is hermetically sealed (airtight).
- Before sending, store the bags in a refrigerator. When they are fresh, green leaflets can be conserved for 15-20 days at 4°C.

DO NOT STORE DRIED LEAFLETS IN PLASTIC BAGS.

DO NOT MIX SAMPLES FROM DIFFERENT TREES.

1b DNA extraction

1. The Extraction buffer should be pre-warmed at 74°C in a water bath before use.
2. Remove the midrib.
3. Weigh 500 mg (450-550 mg) of fresh leaf sample (250 mg dried leaf sample or 200 mg lyophilized leaf).
4. Put purified sand (500-600 mg) and Polyvinylpolypyrrolidone (PVP) (130-160 mg) in a mortar.

If it's possible to use liquid Nitrogen

5. Put liquid nitrogen in the mortar and cut rapidly the weighed sample into very small pieces (approximately 1 mm).
6. Carefully add liquid nitrogen and crush the sample to a fine powder with the pestle. Crush gently at first to avoid splashing.
7. Transfer the powder (green) to a plastic test tube and place it in liquid nitrogen.
8. Step no. 5, 6 and 7 should be done quickly to prevent oxidation/browning of the sample.
9. Add 5 ml pre-warmed *Extraction buffer to the powder and mix thoroughly (preferably using a vortex shaker).
10. Incubate at 74°C for 30 minutes. Mix by inverting or shaking every 5 minutes.

If it's not possible to use liquid Nitrogen

5. Crush the sample with few buffer (1 ml) to obtain a paste. (The paste should not become brown).
6. Then add 4 ml of buffer, mix until obtaining a liquid and uniform green paste.
7. Pour the green solution into a 15 ml test tube.
8. Incubate at 74°C for 30 minutes. Mix by inverting or shaking every 5 minutes.

In both cases

11. Allow the samples to cool to room temperature.
12. Add 5 ml *Chloroform/Isoamyl alcohol (*CIAA; 24:1 v/v) to each sample and mix by inverting 50 times. CAUTION: Care should be taken when handling this chemical as it is poisonous.
13. Centrifuge at 4000 rpm for 15 minutes.
14. Using a pipette, transfer the supernatant to a new test tube.
15. Add 0.7 ml isopropanol per 1.0 ml supernatant and mix gently by inverting to precipitate the DNA.
16. Remove the precipitated DNA using a glass hook, dry it onto an absorbant paper and transfer to a microtube containing 1.0 ml TE/2* (Tris-EDTA Buffer diluted 2 times in water).

Reagents required for DNA extraction

Extraction buffer

To make 100 ml Extraction buffer, weigh the following chemicals, dissolve each separately in a small amount of distilled water, then mix them together and make the final volume to 100 ml by adding distilled water.

	Final concentration	For 100 ml
Tris	100 mM (pH 8 with HCl)	1.21 g
NaCl	1.4 M	8.1 g
EDTA	20 mM	0.8 g
MATAB	2%	2.0 g
PEG 6000	1%	1.0 g
Sodium sulphite	0.5%	0.5 g
Distilled H_2O	to	100 ml

If using concentrate solutions

	For 500ml solution	For 1 litre solution
Tris 1M	50 ml	100 ml
NaCl 5M	140 ml	280 ml
EDTA 500mM	20 ml	40 ml
MATAB	10 g	20 g
PEG	5 g	10 g
Na Sulfite	2.5 g	5 g
Distilled H_2O	to 500ml	to 1000 ml

Chloroform-isoamyl alcohol (CIAA; 24:1 v/v)

To 24 ml chloroform, add 1 ml isoamylalcohol and mix thoroughly.

TE/2 buffer

	Final concentration	For 10 ml
Tris	5 mM	6 mg
EDTA	0.5 mM	2 mg
	pH 8	

1c: Quantification and dilution

The quality and concentration of the DNA is determined by agarose gel electrophoresis. For this, 1 µl of each DNA sample is mixed with 8 µl distilled water and 1 µl 10x *DNA loading buffer and then loaded into the wells of a 1% agarose gel (1 g agarose per 100 ml 1x *TBE buffer containing 0.5 µg/ml ethidium bromide). **CAUTION:** ethidium bromide is highly toxic!

Known standard concentrations of DNA are also loaded onto the agarose gel for comparisons to be made. There are many different standards that can be used, for example, the 1 kb ladder (ref Invitrogene n° 15615-024) or λ uncut DNA (Sigma; D-3779), loaded at several different concentrations (1, 0.5, 0.25 and 0.1 µg). The agarose gel is then run in 1x TBE buffer at 90 V for 2 h or 30 V overnight and the DNA is observed on a UV transilluminator and images recorded.

The DNA samples are compared with the known standards and then a proportion is diluted to 5ng/µl with TE/2 buffer. This is the working solution for the PCR amplification. DNA stock solutions and working solutions are stored at -20°C.

Reagents required for agarose gel electrophoresis

10x DNA loading buffer

	Final concentration		For 250 ml
Tris (HCl to pH 8)	100 mM		3 g
EDTA	100 mM		10 g
Xylene cyanol	0.25%		0.625 g
Bromophenol blue	0.25%		0.625 g
Saccharose	50 %		125 g
Distilled water		to	250 ml

10x TBE buffer

	Final concentration	For 1 litre
Tris	0.89 M	108 g
Boric ac	0.89 M	55 g
EDTA	0.025 M	93 g
Distilled water	to	1000 ml

For 1x TBE buffer, the 10x TBE buffer is diluted 10-fold with distilled water.

1d: PCR Amplification

Primer stock solutions

- Primers can be obtained, purified by desalting, from many commercial companies for use in the microsatellite assay.
- Each primer is diluted to a stock concentration of 100 µM (using distilled water). Stock solutions are stored at –18°C.
- Stock solutions are further diluted to a working concentration of 1 µM (using distilled water). Working solutions are stored at 4°C.
- For PCR amplification, the working solutions for the primers and the DNA are 1 µM and 5 ng/µl, respectively.

PCR assay

Aliquot DNA

- Use 96 well PCR plates. Pipette 5 µl of DNA working solution (5 ng/µl = 25 ng) for each sample into the bottom of each well. As a negative control, set up one well more where NO DNA is added and instead put 5 µl distilled water into the well. ALWAYS include a negative control, no products should be amplified in this control. Seal plates tightly and place on ice whilst making the following master mix.

Standard PCR Master Mix

- The amounts shown below are for one DNA sample only but these amounts can be multiplied by the no. of samples to be tested + 2 (to be sure the volume is enough). This is done so that all the reagents added in the PCR amplification are consistent across all the samples tested.

	Per 25 µl PCR reaction	Final concentration
10x PCR Buffer	2.50 µl	1x
dXTP (2.5mM)	2.00 µl	200µM
Forward primer (1 µM)	5.00 µl	0.2 µM
Reverse primer (1 µM)	5.00 µl	0.2 µM
$MgCl_2$ (50mM)	0.25 µl	0.5+1.5=2 mM
***Taq* polymerase (2 U/µl)**	0.50 µl	1 U
H_2O	4.75 µl	
Total volume of PCR mix:	20.0 µl	

- Add the reagents together, as listed above, in a 5 ml test tube, mix thoroughly and centrifuge briefly (full speed for 10 secs).
- Add 20 µl of PCR master mix to each well containing DNA and to the negative control and seal plates tightly.

NOTE: Once the *Taq* polymerase has been added to the master mix, it is important to work quickly so that the PCR amplification can be started as soon as possible.

1d: PCR Amplification (cont'd)

- PCR plates are immediately loaded into the PCR thermal cycler (for example model PTC 100 by MJ Research, Inc)
- All primers used in this kit will anneal at 51°C using the following PCR programme:

1 cycle:	94°C for 5 minutes
35 cycles:	94°C for 30 seconds 51°C for 1 minute 72°C for 1 minute
1 cycle:	72°C for 30 minutes

1e: Denaturing polyacrylamide gel electrophoresis

- PCR products (microsatellites) are separated on 5% denaturing polyacrylamide gels using 1x TBE buffer.

- The gel mix is made as follows:

		For 4000 ml gel solution
Urea (Merck 1.08.488.1000)		1812 g
10 x TBE		200 ml
40% (19:1 ratio) acrylamide (Eurobio 018808)		500 ml
Distilled water	to	4000 ml final volume

- Only adjust the final volume when the urea has completely dissolved
- When ready to pour gel, add 60 ml gel solution, 250 µl (0.1 g ml^{-1}) ammonium persulfate + 80 µl TEMED and mix briefly. Be quick to pour gel.
- Allow the gel to set for at least 1 hour.
- Pre-warm gel for 20-30 minutes at 55V
- Add an equal volume of 2X *gel loading buffer to each PCR well from the amplification, denature the PCR products at 94°C for 3 minutes before loading gel.
- Using a 62-well comb makes it possible to use a multichannel pipette for loading the samples.
- For each gel (for each microsatellite marker used with the same set of samples), the loading pattern must be identical. For a 62-well gel, the recommended scheme is:

  Marker-Size Ladder, sample1, sample2...sample10, T1, sample11, ...sample 20, T2, sample 21,...sample 30, T1, sample 31,...sample 40, T2, sample 41,...sample 50, T1, sample 51...sample 54.

  Where T1 and T2 are the two standard DNA (T1= WAT4 tree M63 2407 and T2 = MYD tree 092 0715, both from M. Delorme research station in Côte d'Ivoire)

- The running conditions are: 120 minutes at 55V per gel (110V for two gels).

1f: Silver staining

The separated PCR products are visualised using the Promega SILVER SEQUENCE™ DNA Sequencing System (Cat no.: Q4130) as follows:

1. Agitate the gel in all the solutions using a flat-bed stirrer.
2. Fix gel in 2 L 10% acetic acid for 30 min. Retain the acid and use to stop the staining reaction later on in step 7.
3. Wash in 2 L distilled water for 2 min., three times.
4. Place in 2 L Silver Nitrate (2 g) with 3 ml 37% formaldehyde for 30 min. (add the formaldehyde only just before it is required).
5. Rinse briefly in distilled water - 10 secs between entering the water and entering the next solution.
6. Place in 2 L cold Sodium Carbonate (60 g) with 3 ml 37% formaldehyde and 400 µl Sodium Thiosulphate (add sodium thiosulphate only just before it is required) and leave until no further bands appear at the top of the gel.
7. Stop the reaction with 1 L 10% acetic acid (saved from step 2).
8. Once the fizzing has stop, rinse in 2 L distilled water for a minimum of 10 min.
9. Allow gel to dry on bench overnight before scanning.

Quality of water is very important for the silver staining step
Do not make up solutions containing the formaldehyde or sodium thiosulphate until just before they are required

1g: Reading gels and scoring the data

Reading gels

- Check the orientation of the gel. Marker/size ladder MUST be on the left.
- Locate the 5 DNA standard controls (3 times T1 and 2 times T2).
- Determine the allele (bands/products) sizes in these controls. These are known genotypes
- Compare the allele sizes in each sample with those in the standard controls.
- Have at least two different people reading the gel independently, to ensure accuracy.

Scoring and analysing the data with Geneclass2.0

The geneclass2.0 software is available on internet: www.montpellier.inra.fr/URLB. The first page is in French but the English version is down. You can find help online.

Geneclass 2.0 is able to understand different data formats (Genetix, Fstat, Genepop) and has also its own formats. To enter new data, the following one is convenient (the data have been truncated to the first 5 loci:

List of loci

```
                E12         A9          B12         C3b         A3

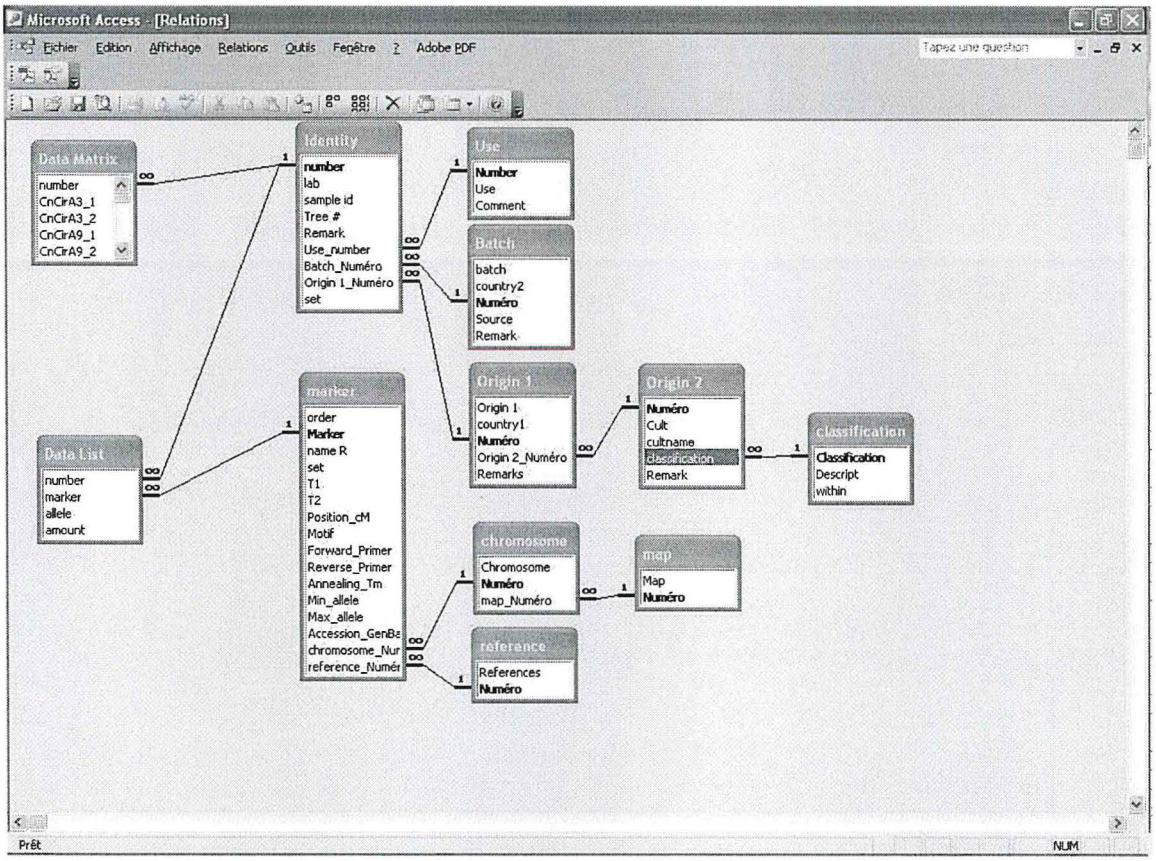
It is possible to multiplexe CnCir E2 and CnCir H4' for running on the gel

Addendum to the technical manual : protocole analyses for fluorescence marking for use with Li-cor

For each SSR marker, one of the primers was designed with a 5'end M13 extension (CACGACGTTGTAAAACGAC) (Steffens et al, 1993). PCR reactions were carried out in 384 wells plates in a 10µl final volume of reaction mixture containing: 25 ng of template DNA, 1X buffer (10mM Tris-HCL pH 8, 50mM KCl and 2 mM $MgCl_2$), 0.2 mM dNTP mix, 0.1U/µl Taq polymerase, 0.08 µM of the M13 labelled primer, 0.1µM of the other primer and 0.1 µM of M13 primer-fluorescent dye IR700 or IR800 (Biolego, The Netherlands). The PCR program started with an initial step of denaturalization at 94°C for 5 min, then 35 cycles of 94°C for 30 s, 51°C for 1min, 72°C 1 min, 72°C for 30 min and stopped after the final elongation at 72°C for 5 min. Each mixture of PCR products contained one IR700 and IR800 labelled M13 reverse complement extensions, diluted to one-fourth with formamid blue; 1.1 µl of the PCR products were separated on 6.5 % on denaturing polyacrylamide gels in a 1X TBE buffer and detected by the IR fluorescence scanning system of sequencer (Li-cor 4300).

Appendix D : Structure of the data base



description of the tables

Table	Comments	Refers to
Identity	Identifies all trees sampled. Each individual is identified by the laboratory where it was analyzed and by a unique number within this laboratory. If available, identification of the tree in the field (or a waypoint) can be stored. Further information is given in the tables represented to the right.	Use Batch Origin1
Use	Describes the possible uses of the molecular data. In principle, only the individuals whose "use" field are set to "diversity" are to be used for diversity studies	
Batch	Identifies set of samples that were sent together to the laboratory. Usually (but not always) the batch descriptors mentions what the sample was supposed to be **before** the analysis.	
Origin 1	Gives a description of the genetic origin of the samples, as confirmed by the analysis. Usually, this corresponds to the "population" level..	Origin 2
Origin 2	Same as origin 1 but corresponds to broader genetic units. Usually (but not always, this corresponds to a cultivar. For diversity studies, the level indicated in the "origin 2" level should be considered as the relevant operational taxonomic unit (OTU).	
Data matrix	A tabular representation of the molecular data. Each marker is allocated two columns. This format is convenient for data inspection and may be used to transfer data to various genetic software.	Identity
Data	A four column representation of the molecular data. This format is convenient to make elementary calculations within the data base.	Identity Marker
Marker	A description of alleles	Chromosome References
Chromosome	List of linkage groups were markers were detected	Map
Map	List of linkage maps (only one for the moment	
References	Bibliographic references	

Appendix E: Summary of the contents of the data base

This appendix lists operational taxonomic units (OTU) represented in the database with the number of individuals studied with either marker set. With a few exceptions, the OTUs correspond to cultivars. There are classified using the three-level classification based on molecular and geographic data.

Group A: Pacific coconuts (Talls and Dwarfs)

Comprises Tall and Dwarf cultivars from South-East Asia, Melanesia, Micronesia and Polynesia.

A1: South East Asian Dwarfs

Table 1: Malayan type Dwarfs (A1a)

Appendix F: Review of the post-training study reports

Country Institution	LOA	Phase and date of last report consulted	Number of trees sampled analyzed	Comments
Results were obtained and may be included into the database				
India CPCRI	APO/03/071	Phase I 30/11/2004	152 analyzed 100 OK	5 collection accessions and 12 farmer varieties. Data were checked and found to be of good quality. At least part of these data could be included.
India CPCRI	APO/04/056	Phase II 26/07/2005	57 analyzed 57 OK	6 collection accessions. Good quality results
Mexico	APO/03/068	Phase I 13/12/2004	140 analyzed 100 OK	10 collection accessions with 9 to 11 primers, 4 farmer varieties with 6 primers Good quality data.
Sri Lanka CRI	APO/04/052	Phase II 30/10/2005	60 analyzed 60 OK	5 collection accessions. Data were checked and found correct.
Brazil Embrapa	APO/04/049	Phase II 17/02/2006	96 analyzed, 72 probably OK	14 accessions of exotic and domestic germplasm in collection represented by 72 individual were analyzed. 24 individuals from farmer's field were added. Data not included in the report and not checked, The dendrogram suggests they should be correct.
Results were obtained but data require further checking				
Côte d'Ivoire CNRA	APO/04/063	Phase II 30/10/2005	197 analyzed	Mainly trees from the collection. Some of them come from Ghana. At several loci, there are discrepancies with what is usually observed at Cirad we don't recommend to include these data unless results are checked.
Tanzania NCDP	APO/03/070	Phase II 30/10/2005	172 analyzed	Six markers were analyzed, we failed to find a correspondence between the data provided and those usually observed in similar germplasm. Data not available, Needs to be checked again.
No results available to us				
Indonesia Balitka	APO/03/072	Phase I 27/12/2004	0	no results
Jamaica CIB	APO/03/076	Phase II 01/07/2005	35	from collection. It is not clear whether results have been obtained
Philippines PCA	APO/03/073	Phase I 12/11/2004	0	At this stage, it seems that no analyzes were done.

Appendix G: Questionnaire

Introduction

Several years ago, the Cogent steering committee proposed that Cirad should serve as a repository for molecular marker data. In fact, molecular markers are an essential tool for the management and utilization of germplasm collection. Their applications in this domain include cultivar genetic structure characterization, assessing the quality of the methods used for rejuvenation and assessing genetic erosion from one generation to another.

This is why Cirad developed a microsatellite kit for coconut cultivar identification under a project sponsored by IPGRI and COGENT. This kit was released in 2002 and comprised 14 microsatellite markers, a data base of 599 individuals characterized with these markers, a manual and statistical software (*geneclass 2*). It was presented to the representatives of 9 producing countries during a training session held in 2003. Since that time, the number of individuals was increased to more than 1000 as well as the number of markers (30 widely used). A large number of population have been sampled, but often with small sample sizes.

Other institutions, including yours have also conducted molecular marker studies. At the request of the COGENT co-ordinator Maria Luz George, I am undertaking to collect information on these studies in order to make them broadly available to coconut breeders, molecular geneticists and genebank curators. This will make it possible to plan the practical use of molecular markers to coconut germplasm survey, maintenance and utilization.

With this survey, I wish to collect several types of information:

- on the molecular marker studies you conducted on coconut,
- on the molecular markers you used,
- on the molecular data matrix (genotyping data), especially on those made with the kit.
- on the papers you published based on these results,
-
-

For the moment, we are especially interested by the data obtained with the microsatellite kit, since they allow a direct comparison between the results obtained in different research centres. However, other molecular data can also be included in the repository.

I thank you in advance for devoting a few minutes to answer the following questionnaire.

Luc Baudouin

Questionnaire

Your name	Bee F. Gunn and Kenneth Olsen
Institution	Australian National University and Washington Univ. St. Louis
Email address	bee.gunn@gmail.com and kolsen@wustl.edu
Date	19/11/2008

1) The studies

Please, list below the molecular marker studies you conducted in coconut. A study is defined by its purpose, a genotype set and a marker set.

Study #	Study name or acronym	Purpose of the study[1]	Brief description	Number of populations or cultivars	Total number of individuals	Marker type(s)[2]	Bibliographic reference(s)[3]
1	Human exploration and dispersal history of the coconut	diversity	comparisons of genotypic diversity of cultivated vs putative wild progenitors of the coconut worldwide and tracing migration routes of the coconut	19	1,238	SSR	
2							
3							
4							
5							
6							

[1]E.g. diversity study, linkage mapping based on mapping population, association study, functional genomics etc.
[2]E.g. microsatellites (SSR), RFLP, RAPD, AFLP, ISTR, DArT etc.
[3]All bibliographic references are to be listed in section 5 below. Please, indicate here the reference number.

2) the markers

Please, describe the different marker sets

Marker type	Number of markers[1]	Total number of alleles[2] or of bands[3]	Bibliographic reference(s)[4]
SSR	10	24,760	

[1]Number of primers, primer pairs or restriction enzymes etc. according to the marker type
[2]For codominant markers
[3]For presence/absence markers
[4]All bibliographic references are to be listed in section 5 below. Please, indicate here the reference number.

3) Studies conducted using the microsatellite kit for characterizing coconut diversity

This marker set was developed by Cirad under an IPGRI-Cogent project.. It is made of the following 14 markers.

CnCirA3, CnCirA9, CnCirB12, CnCirB6, CnCirC12, CnCirC3', CnCirC7, CnCirE10, CnCirE12, CnCirE2, CnCirF2, CnCirG11, CnCirH4' and CnCirH7

More than 2000 individuals representing more than 100 cultivars were characterized with this marker set and a data matrix will be made available soon in a *public* database. for about 1500 of them.

- Did you study coconut genetic diversity using these markers?
  Yes/no
- If so, indicate here the study name(s) as in section 1 above
- **Human exploration and dispersal history of the coconut**
- Are you willing to join the genotyping data into the above described database?
  Yes/no
- If not, could you please explain why?

4) Your suggestions for improving synergy among coconut molecular geneticists, breeders and genebank managers
I would like to suggest a list of repositories for coconut specimens with variety names, including fruits, and silica-gel dried leaf material for DNA.

5) Scientific publications

Please list your publications on coconut molecular marker studies
